

Center for Health Statistics

December 2003

DATA SUMMARY No. DS03-12001

This Data Summary is one of a series of leading cause of death reports.

Highlights

- In 2001, 84.3
 percent of all heart
 disease deaths in
 California occurred
 among people aged
 65 and older.
- During 2001 the California heart disease age-adjusted death rate of 225.9 was lower than the United States rate of 247.7.
- In 2001 Blacks had a heart disease age-adjusted death rate significantly higher than Hispanics, Asian/Other, and Whites.

Heart Disease Deaths in California, 2001

By Daniel H. Cox

Introduction

Heart disease has historically been the leading cause of death in the United States and in California. In 1997, 15 million cases of heart disease were diagnosed in the United States and in 2000, 4.4 million hospital discharges were attributed to heart disease.¹ There were 699,697 heart disease deaths in the United States in 2001.²

This report presents data on heart disease deaths in California during 2001 and provides analysis of crude and age-adjusted death rates for California residents by sex, age, race/ethnicity, and county. The definition of heart disease used in this report is based on the International Classification of Diseases, Tenth Revision (ICD-10) codes I00-I09, I11, I13, and I20-I51 currently presented in National Center for Health Statistics (NCHS) reports.³ The national health objective for heart disease, as defined by the Healthy People 2010 goals, pertains to coronary heart disease (a narrowly defined subset of heart disease). Therefore, an assessment of California's progress in meeting this objective cannot be monitored with the data presented in this report. An analysis of California's progress in meeting the national health objective for coronary heart disease is presented in other Center for Health Statistics (CHS) reports.⁴

Heart Disease Deaths

Table 1 (page 8) displays heart disease death data for 2001 by race/ethnicity, age, and sex. During this period, the number of deaths attributed to heart disease was slightly higher among females (35,080) than among males (33,924). As shown in **Figure 1** (page 2), the number of heart disease deaths among Whites (52,205) was much higher than Hispanics (7,069), Blacks (5,366), and Asian/Other (4,364).

³ National Center for Health Statistics, Deaths: Preliminary Data for 1999, National Vital Statistics Reports DHHS Publication Number (PHS) 2001-1120, PRS 01-0358, June 2001; Volume 49, Number 3.

⁴ Schmidt C., Wilson C. County Health Status Profiles 2003. Center for Health Statistics, California Department of Health Services, April 2003.

A brief overview of data limitations and qualifications is provided at the end of this report.

Heart disease deaths occur predominantly among the older population, and this held true in 2001 with 84.3 percent of all heart disease deaths involving people aged 65 years and older. This age group, within each respective race/ethnic group, accounted for 87.2 percent of all heart disease deaths among Whites, 82.4 percent among Asian/Other, 76.3 percent among Hispanics, and 68.8 percent among Blacks.

Heart Disease Crude Death Rates

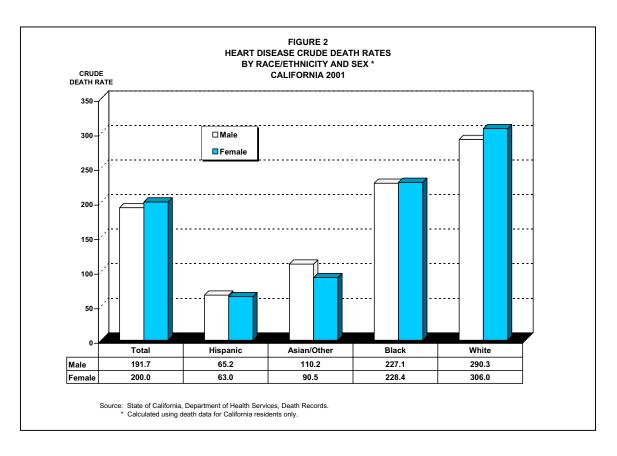

The heart disease crude death rate for California decreased from 197.8 deaths per 100,000 population in 2000 to 195.8 in 2001.⁵ This difference was not statistically significant. As shown in **Table 1** (page 8), Whites had the highest crude death rate in 2001, a rate of 298.3. Blacks were next with a crude rate of 227.8, followed by Asian/Other with a rate of 100.2 and Hispanics with a rate of 64.1. Three of these four rates increased from 2000 when Blacks had a heart disease crude death rate of 226.3, Asian/Other had a rate of 100.1, and Hispanics had a rate of 63.2. The rate for Whites decreased from 2000, when the rate was 300.1. None of these differences between the 2000 and 2001 rates were statistically significant.

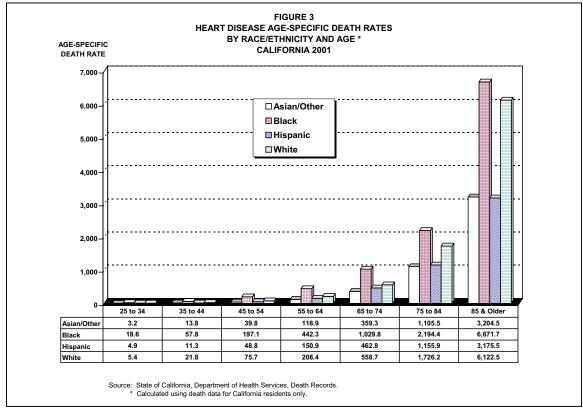

Figure 2 (page 3) shows White and Black females had higher heart disease crude death rates than males in the corresponding race/ethnic groups. White females had a rate of 306.0 deaths per 100,000 population, and White males had a rate of 290.3. Black females had a rate of 228.4 and Black males had a rate of 227.1. Only the difference between White males and females was statistically significant. Contrary to the findings for the other two race/ethnic groups, Asian/Other males had a heart disease crude death rate of 110.2, which was significantly higher than the rate of 90.5 for Asian/Other females.

⁵ Cox D. Heart Disease Deaths in California, 2000. Data Summary. Center for Health Statistics, California Department of Health Services, May 2003.

See the Methodological Approach Section later in this report for an explanation of crude, age-specific, and ageadjusted death rates.

Figure 2 also shows Hispanic males had a rate of 65.2 and Hispanic females had a slightly lower rate of 63.0, though the difference between Hispanic males and females was not statistically significant.

See the Vital Statistics Query System (VSQ) at our Web site www.dhs.ca. gov/hisp/Applications/vsq/vsq.cfm to create your own vital statistics tables.

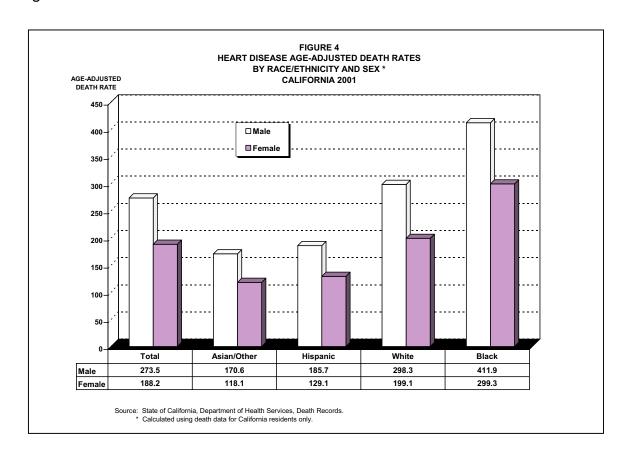

Heart Disease Age-Specific Death Rates

In **Table 1** (page 8) reliable age-specific rates show that among the sexes in 2001, males in all four race/ethnic groups had higher heart disease death rates than females in the corresponding race/ethnic groups. The only exception to this pattern was among the Asian/Other race/ethnic group in the 85 and Older age group where females had a slightly higher heart disease death rate than males.

Figure 3 (page 3) shows that in 2001, among the age groups with reliable rates, Blacks had higher heart disease age-specific death rates than the other three race/ethnic groups. These differences were statistically significant in every age group displayed in **Figure 3**. Not shown in **Figure 3**, but displayed in **Table 1** are the age-specific death rates for the Under 1 age group where Hispanics had the only reliable rate and the 15 to 24 age group where Whites and Hispanics shared the same reliable rate.

Heart Disease Age-Adjusted Death Rates

In 2001 the California heart disease age-adjusted death rate of 225.9 deaths per 100,000 population was lower than the United States rate of 247.7.² The California rate decreased from 2000 when the rate was 231.1.⁵ This difference was statistically significant.

Displayed in **Table 1** (page 8), a comparison among the race/ethnic groups shows that in 2001 Blacks had a heart disease age-adjusted death rate (348.0) significantly higher than Whites (242.4), Hispanics (154.4), and Asian/Other (141.7).

You can read more about crude and age-adjusted rates on the National Center for Health Statistics Web site at www.cdc.gov/nchs/

As shown in **Figure 4** (page 4), in 2001 the heart disease age-adjusted death rate for males was higher than for females in all four race/ethnic groups. Black males (411.9) had a higher rate than Black females (299.3). White males (298.3) had a higher rate than White females (199.1). Hispanic males (185.7) had a higher rate than Hispanic females (129.1), and Asian/Other males (170.6) had a higher rate than Asian/Other females (118.1). All of these differences were statistically significant.

Heart Disease Death Data for California Counties

Table 2 (page 9) displays the number of deaths, crude death rates, and age-adjusted death rates by county averaged over a three-year period, 1999 to 2001. This averaging is done to reduce the large fluctuations in the death rates that are inherent among counties with a small number of events and/or population.

The highest average number of heart disease deaths occurred in Los Angeles County (19,621.3) and the lowest in Alpine County (1.0).

The highest and lowest reliable heart disease crude death rates were in Lake County (362.9 deaths per 100,000 population) and San Benito County (129.9), respectively.

The ranking for heart disease age-adjusted death rates showed Yuba County with the highest reliable rate (292.0 deaths per 100,000 population) and San Benito County with the lowest (153.0).

Heart Disease Death Data by City Health Jurisdiction

Table 3 displays the number of deaths and crude death rates for California's three city health jurisdictions averaged over a three-year period, 1999 to 2001. Age-adjusted death rates were not calculated for the city health jurisdictions because city population estimates by age were not available.

TABLE 3 HEART DISEASE DEATHS AMONG THE CITY HEALTH JURISDICTIONS* CALIFORNIA, 1999-2001

CITY	NUMBER		CRUDE	
HEALTH	OF DEATHS	2000	DEATH	
JURISDICTION	(Average)	POPULATION	RATE	
BERKELEY	470.2	402.742	472.6	
BERKELET	178.3	102,743	173.6	
LONG BEACH	1,129.0	461,522	244.6	
PASADENA	404.0	133,936	301.6	

Note: Rates are per 100,000 population. Data is ICD-10 codes 100-109, I11, I13, I20-I51.

Source: State of California, Department of Finance, Report E-4,
2000 Revised Historical Estimates of California Cities and Counties, March 2002.
State of California, Department of Health Services, Death records.

^{*} Calculated using death data for California residents only.

For more data, see DHS Center for Health Statistics, Home Page at www.dhs.ca. gov/org/hisp/chs/chsindex.htm

The city of Long Beach had an average of 1,129.0 heart disease deaths, Pasadena had 404.0, and Berkeley had 178.3.

Pasadena had a heart disease crude death rate of 301.6 deaths per 100,000 population, Long Beach had a crude rate of 244.6, and Berkeley had a crude rate of 173.6.

Methodological Approach

The methods used to analyze vital statistics data are important. Analyzing only the number of deaths has its disadvantages and can be misleading because the population at risk is not taken into consideration. Crude death rates show the actual rate of dying in a given population, but because of the differing age compositions of various populations, crude rates do not provide a statistically valid method for comparing geographic areas, sexes, race/ethnic groups, and/or multiple reporting periods. Age-specific death rates are the number of deaths per 100,000 population in a specific age group, and are used along with standard population proportions to develop a weighted average rate. This rate is referred to as an age-adjusted death rate and removes the effect of different age structures of the populations whose rates are being compared. Age-adjusted death rates therefore provide the preferred method for comparing different race/ethnic groups, sexes, and geographic areas and for measuring death rates over time. The year 2000 population standard is used as the basis for age-adjustments in this report.

Data Limitations and Qualifications

The heart disease death data presented in this report are based on vital statistics records with ICD-10 codes I00-I09, I11, I13, and I20-I51 as defined by the NCHS.³ Deaths by place of residence means that the data include only those deaths occurring among residents of California and its counties, regardless of the place of death.

The term "significant" within the text indicates statistically significant based on the difference between two independent rates (p<.05).

As with any vital statistics data, caution needs to be exercised when analyzing small numbers, including the rates derived from them. Death rates calculated from a small number of deaths and/or population tend to be unreliable and subject to significant variation from one year to the next. To assist the reader, 95 percent confidence intervals are provided in the data tables as a tool for measuring the reliability of the death rates. Rates with a relative standard error (coefficient of variation) greater than or equal to 23 percent are indicated with an asterisk (*).

Beginning in 1999, cause of death is reported using ICD-10.⁶ Cause of death for 1979 through 1998 was coded using the International Classification of Diseases, Ninth Revision (ICD-9). Depending on the <u>specific cause of death</u>, the number of deaths and death rate are not comparable between ICD-9 and ICD-10. Therefore, our analyses do not combine both ICD-9 and ICD-10 data.

World Health Organization. International Statistical Classification of Diseases and Related Health Problems. Tenth Revision. Geneva: World Health Organization. 1992.

Some of the earlier reports on this subject are available online.

The four race/ethnic groups presented in the tables are mutually exclusive. White, Black, and Asian/Other exclude Hispanic ethnicity, while Hispanic includes any race/ethnic group. In order to remain consistent with the population data obtained from the Department of Finance, the "White race/ethnic group" includes: White, Other (specified), Not Stated, and Unknown; and the "Asian/Other race/ethnic group" includes: Aleut, American Indian, Asian Indian, Asian (specified/unspecified), Cambodian, Chinese, Eskimo, Filipino, Guamanian, Hawaiian, Hmong, Japanese, Korean, Laotian, Other Pacific Islander, Samoan, Thai, and Vietnamese. In addition, caution should be exercised in the interpretation of mortality data by race/ethnicity. Misclassification of race/ethnicity on the death certificate may contribute to death rates that may be underestimated among Hispanics and Asian/Other.⁷

Beginning in 2000, federal race/ethnicity reporting guidelines changed to allow the reporting of up to three races on death certificates. The race/ethnic groups in this report were tabulated based on the first listed race on those certificates where more than one race was listed. Race groups for 2000 and 2001 are therefore not strictly compatible with prior years and trends should be viewed with caution.

Effective with 1999 mortality data, the standard population for calculating age adjustments was changed from the 1940 population standard to the year 2000 population standard, in accordance with new statistical policy implemented by the NCHS. The new population standard affects measurement of mortality trends and group comparisons. Of particular note are the effects on race comparison of mortality. Age-adjusted rates presented in this report are not comparable to rates calculated with different population standards.

In addition, the population data used to calculate the crude rates in **Table 3** (page 5) differ from the population data used to calculate the crude rates in **Table 2** (page 9). Consequently, caution should be exercised when comparing the crude rates among the three city health jurisdictions with the rates among the 58 California counties. Age-adjusted rates for local city health jurisdictions were not calculated.

For a more complete explanation of the age-adjusting methodology used in this report, see the "Healthy People 2010 Statistical Notes" publication.⁹ Detailed information on data quality and limitations are presented in the appendix of the annual report, "Vital Statistics of California." Formulas used to calculate death rates are included in the technical notes of the "County Health Status Profiles" report.¹¹

Note: Rates are per 100,000 population. ICD-10 codes 100-109, I11, I13, I20-I51. White, Black, and Asian/Other exclude Hispanic ethnicity.

Hispanic includes any race category.

The race/ethnic groups in this table were tabulated using the first listed race when certificates included more than one race.

Death rate unreliable, relative standard error is greater than or equal to 23 percent.

Source: State of California, Department of Finance; 2001 Population: Population Projections by Age, Race/Ethnicity and Sex, December 1998. State of California, Department of Health Services, Death Records.

Standard error indeterminate, death rate based on no (zero) deaths. Confidence limit is not calculated for no (zero) deaths.
